Disrupted diurnal patterns in vertebrate reproduction: a neglected feature of the murine two-generation study. Many reproductive toxicology studies are based on their ability to detect effects on reproductive parameters. In vitro and in vivo studies also often depend on the assessment of post-implantation embryos/fetuses at the end of the study. In vivo studies with mice, however, are typically terminated when adult offspring have been produced. This makes it difficult to assess effects on the reproductive capacity of the population. Mice have a diurnal mating rhythm, with peak mating occurring in the dark and a nadir in the light. Moreover, it is well established that diurnal variation in reproductive physiology occurs in a range of other species. The aim of this study was to investigate whether a diurnal variation in post-implantation embryo/fetal development exists in mice. Two experiments were performed to assess the development of embryos from mice mated in the dark or in the light. It was found that dark-mated females were able to establish pregnancy, whilst light-mated females displayed reduced fertility. It was concluded that a diurnal rhythm in reproductive physiology is disrupted by light/dark mating in mice.Q:
